ABSTRACT

Childhood primary angiitis of the central nervous system (cPACNS) is a rare inflammatory brain disease of unknown etiology. Of note, brain hemorrhage has been rarely reported in cPACNS patients, generally associated with a delayed clinical diagnosis, or with a diagnosis only at necropsy. We present the case of a boy with cPACNS that previously suffered an ischemic stroke. At the age of 7 years and 10 months, he presented a sudden and severe headache, vomiting and reduction in consciousness level (Glasgow coma scale 7), requiring prompt tracheal intubation. Brain computed tomography demonstrated intraparenchymal hematoma in the right parieto-occipital lobe and a small focus of bleeding in the right frontal lobe, vasogenic edema, herniation of the uncus and a 10 mm deviation to the left from the midline. C-reactive protein (9.2 mg/dL) and von Willebrand factor (vWF) antigen (202%) were elevated. Decompressive craniotomy was performed and methylprednisolone and cyclophosphamide were administered. One week later, the patient had left hemiparesis without other sequelae. Importantly, motor deficits have been improving progressively. Our case reinforces the inclusion of this vasculitis as a differential diagnosis in children and adolescents with CNS hemorrhage.

Hemorragia intracerebral com evolução favorável em paciente com angitié primária do sistema nervoso central juvenil

RESUMO

Angitié primária do sistema nervoso central juvenil (APSNCJ) é uma doença inflamatória cerebral rara e de etologia desconhecida. Hemorragia cerebral tem sido raramente repor-
tada em pacientes com APSNCJ, geralmente associada com atraso diagnóstico, ou com um...
Introduction

Vasculitides are characterized by inflammation and necrosis of endothelium. They can affect blood vessels of any organ and system, including the central nervous system (CNS). CNS vasculitis most often is secondary to an underlying condition, such as infectious, neoplastic, vascular, metabolic or inflammatory disorders, but it also can be idiopathic.

Of note, childhood primary angitis of the CNS (cPACNS) is a rare inflammatory brain disease of unknown etiology that occurs in previously healthy children. It has protean clinical manifestations, such as seizures, cognitive dysfunction, behavior changes, headaches, neurologic deficits and strokes.

Ischemic stroke seems to occur more often than hemorrhagic events, which are seldom described in the literature. As far as we are concerned, only seven cases were reported regarding hemorrhagic stroke and cPACNS in the literature, most of which had delayed clinical or necropsy diagnosis.

We describe a patient with cPACNS and intracerebral hemorrhage submitted to prompt drainage and immunosuppressive therapy with good prognosis.

Case report

At the age of 7 years and 2 months, a boy presented intense headache during about 5 minutes with spontaneous improvement. In the next twenty-four hours, he had labial commissure deviation to the right side and left hemiparesis, being hospitalized in another hospital. Laboratory exams were: hemoglobin 12.7 g/L, hematocrit 36%, white blood cell count 10,300/mm³ (neutrophils 39%, lymphocytes 52%, monocytes 5% and eosinophils 4%), platelets 300,000/mm³, urea 30 mg/dL (normal range 10-50), creatinine 0.53 mg/dL (normal range 0.32-0.60), C-reactive protein (CRP) 1.1 mg/dL (normal < 5), erythrocyte sedimentation rate (ESR) 7 mm/1st hour (normal range 0-20) and activated partial thromboplastin time 27.2 s, International Normalized Ratio (INR) 1.1. Homocysteine levels were 5.5 micromol/L (normal range 5-15), total cholesterol 176 mg/dL (normal <200), low-density lipoprotein cholesterol 112 mg/dL (normal <100), high-density lipoprotein cholesterol 49 mg/dL (normal > 40) and triglycerides 79 mg/dL (normal <150). Brain magnetic resonance imaging (MRI) showed ischemic areas in the right middle cerebral artery territory, characterized by subcortical foci of restricted diffusion in the nucleocapsular region, whereas carotid and vertebral magnetic resonance angiography, conventional angiography and carotid Doppler ultrasound were unremarkable, as well as cerebrospinal fluid analysis. Immunological tests were positive for antinuclear antibodies (ANA) 1:80 (fine dense speckled pattern) and negative for other serum antibodies: anti-double stranded DNA (anti-dsDNA), anti-Sm, anti-RO, anti-La, antinuclear antibodies (anti-ENA), IgG, lupus anticoagulant, anti-β2-glycoprotein-1 and antineutrophil cytoplasmic antibodies. Urinalysis was normal, and blood culture was negative. Protein C (115%), protein S (126%) and factor VIII (87%) activities were within the normal range. Factor V Leiden mutation and prothrombin gene polymorphism were both absent. Aspirin (5.0 mg/kg/day) was introduced, and after 4 months of rehabilitation physiotherapy, complete recovery of the motor deficits was achieved and aspirin was withdrawn. At the age of 7 years and 8 months, he returned asymptomatic in an outpatient visit, bringing a new brain MRI that revealed encephalomalacia in the right nucleocapsular region and leptomeningeal enhancement in the left precentral sulcus, left central sulcus, right occipital sulcus, sphenoid portion of the right Sylvian fissure and inferior aspect of the cerebellar hemispheres, compatible with CNS angitis (Fig. 1). Prophylactic aspirin was reintroduced, and he was referred to our University Hospital. At that moment, the patient did not have complaints. He had normal weight and height development. Peripheral artery pulses were palpable, there was no claudication of extremities, and blood pressure was 99 × 65 mmHg, without differences in the limbs. No right-left shunt was observed during echocardiography with microbubbles, CRP was 0.9 mg/dL, and ESR was 11 mm/1st hour. At the age of 7 years and 10 months, he had a sudden and severe headache, vomiting and reduction in consciousness level (Glasgow coma scale 7), requiring prompt tracheal intubation. Urgent brain computed tomography demonstrated intraparenchymal hematoma in...
the right parieto-occipital lobe (Fig. 2) and a small focus of bleeding in the right front lobe, vasogenic edema, uncal herniation and a 10 mm deviation from the midline to the left. Decompressive craniotomy was promptly performed, and cerebral specimen was obtained for histopathological study. Methylprednisolone pulse therapy for three consecutive days (1.0 g/day) was administered, followed by cyclophosphamide 500 mg/m² of body surface. Laboratory tests showed hemoglobin 13.1 g/L, hematocrit 39.7%, white blood cell count 23,300/mm³ (neutrophils 88%, lymphocytes 5%, monocytes 6% and 1% eosinophils), platelets 352,000/mm³, urea 23 mg/dL, creatinine 0.37 mg/dL, ESR 8 mm/1ST hour, activated partial thromboplastin time 0.91 s, and INR was 1.27. The CRP was elevated (9.2 mg/dL), and vWF antigen was 202% (normal range 50-160%). New immunological tests for detection of anticardiolipin IgM, anticardiolipin IgG and lupus anticoagulant were persistently negative in three occasions. Biopsy revealed large quantity of blood clots containing several fragments of cerebral tissue with gliosis, with no evidence of active vasculitis. After a week of hospitalization, he still had left hemiparesis, but no other sequelae; he was discharged with prednisone 2 mg/kg/day. One month after the neurosurgery, prednisone was tapered to 1.5 mg/kg/day, and a new dose of cyclophosphamide 500 mg/m² was administered. The vWF antigen was 108%, and ESR, 5 mm/1ST hour. Importantly, motor deficits are progressively improving, with very light left hemiparesis and left hemianopsia, without apparent cognitive dysfunction.

Discussion

We describe herein a case of cPACNS that presented hemorrhagic event with a favorable outcome after prompt drainage and immunosuppressive therapy. The association of cPACNS and hemorrhagic stroke has been reported only in seven cases in the literature, mostly with poor outcome associated with death or severe disabilities.\textsuperscript{1,4-8}

cPACNS shows inflammation only in CNS vessels, without involvement of other organs and systems. Moreover, this illness is not associated with secondary CNS vasculitis, caused by infection, other inflammatory diseases, vascular, metabolic and neoplastic etiologies.
Interestingly, the inflammatory markers, such as CRP and ESR, may help to assess disease activity, although these exams may oscillate during the disease course. The vWF antigen has been described as a reliable biomarker for patients with active systemic vasculitis. It is a plasma protein synthesized by megakaryocytes and an endothelial cell that reaches higher levels in the presence of damaged or inflamed vascular endothelium.\(^2,\)\(^11\) Moreover, increased levels of vWF antigen were reported in 65% of c-PACNS population. Remarkably, these levels decreased significantly after treatment, as observed herein.\(^1\)

Additional detections of antiphospholipid antibodies were prospectively collected, since these antibodies may fluctuate during the disease course, reaching non-detectable levels at the acute vascular events.\(^12\)

The early neurosurgical treatment in conjunction with immunosuppressant provided favorable outcome for our patient. Indeed, the therapy for SV-cPACNS includes induction with glucocorticoids and intravenous cyclophosphamide during the first six months and subsequent maintenance therapy with mycophenolate mofetil for 18 months.\(^2,\)\(^13\)

In conclusion, we reported a favorable prognosis in a SV-cPACNS patient with brain hemorrhage, reinforcing the inclusion of these vasculitis as a differential diagnosis in children and adolescents with CNS hemorrhage.
