DOI: <http://dx.doi.org/10.1590/abd1806-4841.20198389>

Dear editor,

We have read with great interest the recent review written by Haddad *et al.* (2018), regarding skin manifestations caused by tick bites, published in *Anais Brasileiros de Dermatologia*, in which the authors propose a clinical classification of these manifestations considering “primary lesions” (PL) and “secondary lesions” (SL).¹ To their list, we would like to suggest the inclusion of two other emerging clinical entities, still little known to health professionals in Brazil: *Rickettsia parkeri* spotted fever (RPSF) as a SL and toxicosis by *Ornithodoros* as a PL.

FIGURE 1: A - A female of *Amblyomma ovale* (Source: Álvaro A. Faccini-Martínez). B - Inoculation eschar in a patient with spotted fever caused by *Rickettsia parkeri* strain Atlantic rainforest. (B - 1) 12 days after the tick bite (DATB). (B - 2) 14 DATB. (B - 3) 23 DATB. (B - 4) 30 DATB (Source: Krawczak, *et al.*, 2016³)

FIGURE 2: A - A female of *Ornithodoros rietcorraei* associated to human parasitism and toxicosis, collected in residences in the urban area of Russas, State of Ceará (Source: Stefan Vilges de Oliveira). B - Skin lesion (heel) by *Ornithodoros brasiliensis* bite, State of Rio Grande do Sul (Source: José Reck Jr., *et al.*, 2013⁷) C - Bullous lesion on the wrist caused by *O. mimon* bite, State of Minas Gerais (Source: Labruna, *et al.*, 2014⁸; by permission of Oxford University Press journal)

Received 24 April 2018.

Accepted 26 July 2018.

RPSF occurs predominantly in Atlantic rainforest areas of South, Southeast, and Northeast Brazilian regions. *R. parkeri* strain Atlantic rainforest is the causative agent of this condition, which is transmitted to humans by *Amblyomma ovale* ticks. (Figure 1A).² Clinical manifestations of *R. parkeri* infection tend to be less severe than *R. rickettsii* rickettsiosis, associated with fever, inoculation eschar, rash, lymphadenopathy, malaise, headache, myalgia, and arthralgia.² Inoculation eschar (main sign) is defined as a painless ulcer lesion with a crusty-necrotic center and a surrounding erythematous halo, measuring 0.5 - 2 cm in diameter, which indicates the site of the tick bite (Figure 1B).^{2,3} Doxycycline is the drug of choice for all suspected spotted fever cases, regardless of age group and disease severity.²

Ornithodoros ticks, in turn, is a genus in the soft-bodied tick family (Argasidae) that has gained medical importance for their ca-

capacity to cause toxicosis,⁴ or for being borreliosis (relapsing fever) vectors.⁵ These ticks are natural parasites of mammals (mainly rodents) and birds living in caves, tree hollows, nests, and attics of houses. Ticks become infected when they feed on animals (primary hosts) that carry the bacterium in their blood. The disease is transmitted to humans by the bite of infected ticks.⁶ In Brazil, toxicosis in humans has been reported in the states of Rio Grande do Sul, Minas Gerais, Goiás, Pernambuco, Rio Grande do Norte, and Ceará, with *Ornithodoros brasiliensis*, *O. mimon*, and *O. rietcorrei* as the related tick species (Figure 2A).⁷⁻⁹ The most common clinical manifestations included local pruritus, edema and erythema, blister lesions, and systemic involvement (transient fever, dyspnea, and malaise) (Figure 2B- C).^{4,7} Topical or systemic corticosteroids and antihistamines may be used as treatment options.⁴

Both clinical entities presented here should be considered in the medical evaluation of tick bite-associated lesions. In such cases, dermatologists may contribute to the diagnosis of these diseases. □

We are grateful for the comments which will certainly enrich the ever-evolving knowledge about tick-borne diseases, both those caused by parts of the tick's mouth remaining in the skin after the bite and the infectious diseases transmitted by the arthropods. We are sure that the letter will draw readers' attention and will fulfill the function intended by the authors. However, it should be clear that the purpose of the article was not to exhaust the subject, but, as a medical text, to propose a practical classification so that dermatologists and other professionals in the field of Tropical Medicine know more about the problem and know how to evaluate later complications caused by the bites. However, due to the constant evolution of studies on tick-borne diseases, the scientific significance of this type of text may be limited (although the most frequent diseases are all approached by the study). On the other hand, the idea of classification based on a clinical observation and consequent therapeutic indication, the primary objective of the work remains – and will remain – current. □
