Implementing an epilepsy surgery center. Initial experience at a university hospital in Brazil

Implementação de um centro de cirurgia de epilepsia. Experiência inicial em um hospital universitário no Brasil

Gabriel Pereira Escudeiro¹, Rafael Teixeira Magalhães Leal¹, Heros Henrique Melo de Almeida¹, Marcus Andre Acioly¹, José Alberto Landeiro¹, Bruno Lima Pessoa¹

ABSTRACT

Epilepsy is a serious neurological condition, often without a full and effective treatment. In some cases, surgery is beneficial, despite being underused. Our aim herein is to describe the implementation of an epilepsy surgery center in a federal university hospital, sharing the initial experience gained, as well as describing the main challenges and first results. **Methods:** Experience report of an epilepsy surgery center implementation. Retrospective review of 13 drug-resistant patients who underwent surgical treatment. **Results:** Thirteen patients underwent surgical epilepsy treatment, five patients categorized as the International League Against Epilepsy class 1, two in class 2, three in class 3, zero in class 4, and two in class 5; with a 30.76% complication rate. **Conclusion:** Despite the challenges, it was possible to implement an epilepsy surgery center with favorable results and acceptable incidence of complications, which were not higher than the incidences found in more experienced centers.

Keywords:epilepsy; neurocirurgical procedures; developing countries.

RESUMO

Epilepsia é um problema neurológico sério e para o qual não há um tratamento efetivo e definitivo. Apesar de o tratamento cirúrgico ser bastante benéfico em alguns casos, ainda é subutilizado. O objetivo deste trabalho é descrever a implementação de um Centro de Cirurgia de Epilepsia em um Hospital Universitário Federal, divulgar a experiência inicial obtida, os principais desafios, as dificuldades e os resultados iniciais. **Método:** Relato da experiência na implementação do Centro de Epilepsia. Análise retrospectiva de série de treze pacientes com epilepsia resistente a medicação e que foram submetidos a tratamento cirúrgico. **Resultados:** Treze pacientes submetidos a tratamento cirúrgico, 5 com a Liga Internacional Contra Epilepsia classe 1, 2 com classe 3, três com classe 3, zero com classe 4 e 2 com classe 5; com uma taxa de complicação de 30, 76%. **Conclusão:** Apesar das dificuldades, foi possível a implementação de um Centro de Cirurgia de Epilepsia com resultados favoráveis e taxas de complicação não superiores aos centros de países desenvolvidos.

Palavras-chave: epilepsia; procedimentos neurocirúrgicos; países em desenvolvimento

Epilepsy is a serious neurological condition, which is often neglected as a major public health problem¹. It was first described approximately 4,000 years ago. Throughout history, it has been considered a contagious disease, or witchcraft, with a demonic or spiritual etiology, for which many treatments have been proposed^{2,3}. Since then, our knowledge regarding epilepsy has greatly increased. Numerous studies have been conducted and novel treatments have been suggested. However, even today, our knowledge remains limited and there is no fully effective treatment for this condition^{2,3}.

Several diagnostic criteria have been indicated for refractory epilepsy. Juul-Jensen defined as refractory seizures those that failed with at least two first-line drugs⁴. Further, Gilman et al. characterized as refractory seizures those in which the first-line anticonvulsant drugs were attempted in their usual doses but did not yield the desired response⁵. The International League Against Epilepsy (ILAE) defines the term "drug resistant epilepsy" as "failure of adequate trials of two tolerated and appropriately chosen and used anti-epileptic drug schedules (whether as monotherapies or in combination) to achieve sustained seizure freedom"⁶.

Approximately 1% of the world's population is affected by epilepsy¹. Unfortunately, there are very few studies regarding the prevalence and incidence of epilepsy in Brazil. It is

Support: This project had FAPERJ's (Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro) incentives.", register: E-26/110.245/2014 Received 31 May 2017; Received in final form 07 July 2017; Accepted 17 July 2017.

estimated that there were 340,000 new epilepsy cases in 2005 and the prevalence reached 1.8 million patients in the country the same year⁷. Depending upon the criteria used, 9% to 24% of the patients are considered inadequately controlled with antiepileptic drugs⁸.

In 1828, Benjamin Dudley reported on one of the first epilepsy surgeries, conducted on a patient who developed seizures after brain trauma. The surgery consisted of decompressive trepanation, and a good result was obtained⁹. In 1886, Sir Victor Horsley, guided by Hughlings Jackson, performed surgery on a 22-year-old man with a long-term epilepsy after an accident resulting in a depressed skull fracture. Horsley found an area of brain scarring, which was resected with a 0.5 cm margin and the patient became seizure free¹⁰. Since then, knowledge regarding epilepsy surgery has increased with contributions from many famous surgeons, highlighted by Fedor Krause, Harvey Cushing, Otfrid Foerster, Wilder Penfield, Herbert Jasper and Paulo Niemeyer¹¹.

Through the years, both pathophysiology and surgical techniques for this disease have greatly improved. Epilepsy surgery has become more effective, especially in patients with mesial temporal atrophy and extratemporal lesions¹². A Cochrane Library meta-analysis found that the group of patients who underwent surgery was 15 times more likely to become seizure free compared with exclusive clinical treatment¹³.

Our aim is to describe the implementation of an epilepsy surgery center at a university hospital in the southeastern region of Brazil. By sharing our initial experience and describing the main challenges found, we hope to stimulate the implementation of new epilepsy surgery centers. In addition, we present the results of a series of patients treated with epilepsy surgery at our institution.

Box 1. Engel surgical outcome classification.

IA: Completely seizure-free since surgery

Class I: Free of disabling seizures

IC: Some disabling seizures after surgery, but free of disabling seizures for at least 2 years ID: Generalized convulsions with antiepileptic drug withdrawal only Class II: Rare disabling seizures ("almost seizure-free") IIA: Initially free of disabling seizures but has rare seizures now IIB: Rare disabling seizures since surgery IIC: More than rare disabling seizures after surgery, but rare seizures for at least 2 years IID: Nocturnal seizures only Class III: Worthwhile improvement IIIA: Worthwhile seizure reduction IIIB: Prolonged seizure-free intervals amounting to greater than half the follow-up period, but not less than 2 years

IB: Non-disabling simple partial seizures only since surgery

Class IV: No worthwhile improvement IVA: Significant seizure reduction IVB: No appreciable change IVC: Seizures worse

METHODS

We reviewed all charts of patients with medically-resistant seizures who underwent a surgical treatment from September 2012 to April 2016. The diagnostic criteria used were those proposed by the ILAE, as previously mentioned.

Regarding the surgical technique, all patients underwent a neuronavigation-based craniotomy. Non-selective amydalohippocampectomy (NSAH), Spencer's technique, was performed for mesial temporal sclerosis, with or without associated tumor. In patients with tumor-associated epilepsy in the mesial portion of temporal lobe, standard tumor resection was performed, associated with NSAH. Lateral temporal lobe tumors and extratemporal ones were treated with tumor resection by standard neurosurgical technique.

All information was obtained from our registry platform (electronic chart). The outcomes of interest were the Engel Classifications after surgery¹⁴ (Box 1) and the ILAE scores¹⁵ (Box 2). Both complications and clinical outcomes were registered.

RESULTS

From September 2012 to April 2016, 13 patients met the inclusion criteria. Eight men and five women were included. The mean age was 33 years old (17 to 57 years), and the follow-up was seven to 43 months, excluding one case of death in the postoperative period. All but one patient had temporal lobe epilepsy, MRI positive findings and concordant EEG.

Demographic data such as age, gender, etiology, laterality, type of surgery and outcome scores are shown in the Table. According to the Engel outcome classification, there were five patients classified as IA, 3 as IB, one IC, one IIC, one IIIB, and one IVB; there were no patients in the other categories (Figure 1). According to the ILAE outcome scale, five patients were class 1, two class 2, three class 3, and two class 5 (Figure 2).

Of the 13 patients who underwent surgery, four (31%) had some sort of complication. One (8%) patient developed a temporal bleed immediately after surgery, which was promptly drained, but this patient eventually died due to pulmonary sepsis. Only one patient (8%) developed symptomatic quadrantanopia, confirmed by complementary examinations. Two (16%) developed a psychiatric disorder; one characterized by childish behavior

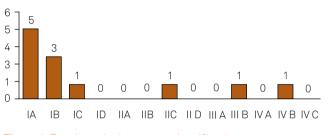

Box 2. International League Against Epilepsy outcome scale.

Class 1: Completely seizure free; no auras Class 2: Only auras; no other seizures Class 3: 1 to 3 seizure days per year; ± auras Class 4: 4 seizure days per year to 50% reduction of baseline seizure days; ± auras Class 5: Less than 50% reduction of baseline seizure days; ± auras Class 6: More than 100% increase of baseline seizure days; ± auras

Table.Demographic data o	f age, gender, etiology	, laterality, type of	surgery and outcome scores.
--------------------------	-------------------------	-----------------------	-----------------------------

Gender	Age	Alteration	Side	Procedure	ILAE	Engel
Male	53	Hippocampal atrophy	Right	NSAH	2	IB
Male	17	Temporal mesial tumor	Right	Resection + NSAH	1	IA
Female	49	Hippocampal atrophy and DNET	Right	Resection + NSAH	3	IB
Male	40	Neocortical temporal-occipital tumor	Right	SR	2	IB
Female	16	Temporal mesial tumor	Right	Resection + NSAH	1	IA
Female	25	Frontal cavernoma	Right	SR	1	IA
Male	39	Hippocampal atrophy	Right	NSAH	1	IA
Female	34	Hippocampal atrophy	Right	NSAH	1	IA
Male	58	Hippocampal atrophy	Right	NSAH	5	IVB
Female	39	Hippocampal atrophy	Right	NSAH	3	IC
Female	24	Hippocampal atrophy	Right	NSAH	3	IIC
Male	49	Neocortical temporal tumor	Right	SR	5	IIIB

and visual hallucinations and one developed depression; both were referred for psychiatric and psychological care.

Considering the difficulties found in the implementation process, we highlight the following:

Firstly, because of the under-referral from other physicians, such as neurologists and general physicians from basic health care centers, it became necessary, in some cases, to actively recruit patients. Furthermore, there were not enough hospital beds, especially ones dedicated to epilepsy patients.

Secondly, there was difficulty accessing video EEG. Although EEG video equipment had been obtained through a research project, there was, at the time, no medical room or personnel (medical and non-medical) for its full operation. Moreover, there was neither transoperative stimulation or electrocorticography in our service.

DISCUSSION

In the United States, in 1987, there were only 26 epilepsy surgery centers. In 1992, this increased to 67 centers¹⁶. Unfortunately, to the best of our knowledge, there is no such data in Brazil. However, it is well known that the number of centers that offer this type of surgery is not enough to care for this country's population. Thus, the implementation of epilepsy surgery centers is critical.

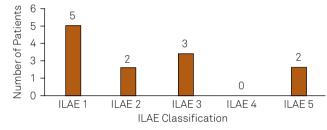

Figure 2. International League Against Epilepsy outcome scale.

Ours is the only public institution with an epilepsy surgery team in a subregion made up by seven cities and a population of 1,857,345¹⁷. It is the referral center for many specialties, including neurosurgery and neurology. When epidemiological data^{1,8,18} is extrapolated to our population, it is estimated that approximately 1,650 to 7,350 refractory epilepsy patients could potentially benefit from surgery, or, at least, a surgical evaluation. However, our sample consisted of only 13 patients, a much lower number compared to the estimated population.

Other authors have reported that, despite the currently available evidence, surgery for refractory epilepsy is underutilized. As Jatté et al. mentioned in their review, that there is a gap between evidence and practice, and that epilepsy surgery is underused in countries such as the USA, UK and Canada. They pointed out some factors that might contribute to the phenomenon: incomplete or biased data, under-referral to surgery centers, access issues, efficacy of new antiepileptic drugs, effectiveness of surgery in children, lack of knowledge and misconceptions, and behavioral or cultural issues¹².

We had similar problems to those experienced by more economically-developed countries, such as under-referral. However, we also have different problems, more typical of developing countries, such as the lack of supplies and hospital beds. This observation is of utmost importance, since the regional characteristics of the health care system impose different issues for the implementation of an epilepsy center. Therefore, we consider the report of the current active epilepsy surgery centers'experiences, as well as the information exchange, to be very important.

Despite the difficulties faced, our patients had good outcomes, as established by the Engel and ILAE classifications, and a relatively low complication rate. De Tisi et al.¹⁹, in a series of 649 patients undergoing surgical treatment for epilepsy in the UK found that 40% became entirely seizure free and 11% improved (simple partial seizure only). Their results were very similar to ours. With respect to complications, they had a 3% mortality, 8% visual field defects in temporal lobe epilepsy, 5% wound infections, <1% hemiparesis; 2% frontalis muscle weakness; 1% dysphasia; 3% cerebro spinal fluid leaks needing intervention, and one deep venous thrombosis, with an overall complication rate of 22%¹⁹.

In a meta-analysis conducted by Téllez-Zenteno et al.²⁰, with data from 76 studies, they found a 66% seizure-free rate after surgery (Engel I) for temporal lobe epilepsy, including tumor and non-tumor diseases. In this same meta-analysis, they found a 46% seizure-free rate after occipital and parietal resections and a 27% seizure-free rate after frontal lobe resections; and 35% of the patients became free of incapacitating seizures after callosotomy²⁰.

Thus, considering that temporal lobe epilepsy has a better outcome after surgical treatment¹⁹, we decided to select patients with this condition, if possible, for our initial experience.

Psychosocial disabilities are more prevalent in patients with refractory seizures, with lower social interaction and reduced marriage rates²¹. Vickrey et al.²² compared the quality of life in patients with epilepsy and other diseases (hypertension, diabetes, heart disease and depression). They concluded that patients who became seizure free after surgery had a better quality of life than the others²².

In a review of the causes of epilepsy-related death, Rufo-Campos²³ listed sudden death, status epilepticus, trauma in general, aspiration pneumonia, drowning and burns. In a study by Ferreira and Silva²⁴, the authors conducted a subsystem information survey on mortality in the Ministry of Health between 1980 and 2003 and found 32,655 deaths to bea direct consequence of epilepsy, which was calculated as an average of 1,236 deaths per year. The authors emphasized that these data are probably underestimated due tounder-reporting²⁴.

Berg et al.²⁵ reported a 20-year delay between the onset of seizures and the referral for surgery evaluation. Sillanpääet al.²⁶ performed a long-term follow-up with 220 children diagnosed with epilepsy in Finland. They pointed out that the most important predictor for seizure control was a rapid response to initial therapy, defined as the reduction of seizures– at least 75% in three months – and when this percentage was not achieved, surgery should be considered.

Considering the lack of a center for epilepsy surgery in our region, we are committed to the implementation of this project. So far, great results have been attained.

We decided to publish our initial results and our major difficulties to encourage other neurosurgical teams, withconditions similar to ours, to implement an epilepsy center.

Epilepsy is a serious health problem and the surgical approach is potentially beneficial for a considerable proportion of patients with this disease, although, in some areasofthe world, the access of these patients to a surgery team is not possible.

In conclusion, we present the implementation of an epilepsy surgery center with favorable results and low incidence of complications (very similar to more developed centers). We believe that, in a region without this resource, neurosurgeons should be encouraged to implement an epilepsy center.
