

Objective short sleep duration is associated with the activity of the hypothalamic-pituitary-adrenal axis in insomnia

Insônia, com tempo de sono curto, medido objetivamente, esta associada a atividade do eixo hipotálamo-hipófise-adrenal

ABSTRACT

Objective: To evaluate the association between objective short sleep duration in patients with insomnia and changes in blood parameters related to hypothalamic-pituitary-adrenal (HPA) axis activity. **Method:** A cross-sectional pilot study was conducted in 30 middle-aged adults with chronic insomnia who were divided into 2 groups according to polysomnography (PSG) total sleep time (TST) (TST > 5h and < 5h). All patients underwent subjective analysis of sleep quality, anthropometric measurements, PSG, and determination of fasting blood parameters. **Results:** The results revealed lower sleep efficiency and higher sleep latency for those with a TST < 5h. The subjective sleep quality was worse in the TST < 5h. Significantly, higher glucose and cortisol levels were observed with a TST < 5h. Glucose, cortisol and ACTH levels were inversely correlated with the PSG total sleep time. **Conclusion:** Patients with insomnia with objective short sleep duration had HPA-associated endocrine and metabolic imbalances chronically linked to increases in cardiovascular risk observed with this more severe insomnia phenotype.

Keywords: insomnia disorder, objective short sleep duration, hypothalamic-pituitary-adrenal axis.

RESUMO

Objetivo: Avaliar a associação entre insônia com tempo de sono curto e alterações sanguíneas relacionados com a atividade do eixo hipotálamo-hipófise-adrenal (HPA). **Método:** Estudo piloto transversal, com 30 adultos de meia-idade, distribuídos em 2 grupos de acordo com o tempo total de sono (TTS) pela polisonografia (PSG) (TTS > 5h e < 5h). Os pacientes foram submetidos a análise subjetiva da qualidade do sono, medidas antropométricas, PSG e parâmetros sanguíneos em jejum. **Resultados:** Revelaram baixa eficiência do sono e maior latência do sono para aqueles com TTS < 5h. A qualidade subjetiva do sono foi pior no TTS < 5h. Significativamente, os níveis de glicose e cortisol mais elevados foram observados no grupo com TTS < 5h. Os níveis de glicose, cortisol e ACTH foram inversamente correlacionados com o TTS da PSG. **Conclusão:** Pacientes com insônia com tempo de sono curto apresentaram desequilíbrios endócrinos e metabólicos associados a atividade do eixo HPA, correlacionados ao aumento do risco cardiovascular observado neste fenótipo mais grave de insônia.

Palavras-chave: transtornos de insônia, curta duração objetiva de sono, eixo hipotálamo-pituitária-adrenal.

Difficulties in initiating or maintaining sleep and associated impairment in daytime activities for a duration of at least six months are the defining features of chronic insomnia, which affects 10% of the population^{1,2,3}. Although insomnia syndrome involves subjective complaints, insomnia with objective short sleep duration [total sleep time (TST) < 5 h, as assessed by polysomnography (PSG)] is possibly a more severe biological phenotype of this sleep disorder and is a predictor for the persistence of this condition⁴.

Insomnia disorder with objective short sleep duration is associated with increasing incidence of hypertension and negatively impacts the variability of blood pressure and heart rate, which has been associated with increased cardiovascular mortality^{5,6,7}. A cross-sectional analysis revealed that insomnia with objective short sleep duration is associated with an increased risk of diabetes⁸. Hypothalamic-pituitary-adrenal (HPA) axis activity plays a role in hypertension and diabetes development^{9,10}. However, data suggesting that HPA hormone levels are higher in insomnia are still inconclusive^{11,12,13}.

Studies targeting more severe insomnia phenotypes with respect to HPA activity may clarify this possible association. This pilot study aimed to evaluate the association between fasting blood parameters related to HPA activity and short sleep time as assessed by PSG in patients with chronic insomnia disorder.

METHOD

This cross-sectional pilot study was conducted at the Sleep Institute of Sao Paulo and at the Federal University of Sao Paulo, Brazil. An initial pre-interview was conducted via telephone, and the first 100 volunteers with insomnia complaints were pre-screened. Of the 100 volunteers, we evaluated 60 patients. Thirty patients of both genders fulfilled the inclusion criteria and were diagnosed with chronic insomnia, adapted from DSM-V criteria¹⁴. Each patient underwent an interview so that the protocol procedures could be explained and signed a consent form to participate in the study. Anonymity was guaranteed during all data collection and reporting. The study protocol was approved by the Federal University of Sao Paulo Ethics Committee, Sao Paulo, Brazil.

The inclusion criteria were an age between 30 and 55 years and diagnosis of chronic insomnia exceeding 6 months. The exclusion criteria were use of psychoactive drugs, history of relevant neurological and psychiatric or medical conditions, shift work, presence of other sleep disorders, significant abnormalities in laboratory tests, apnea/hypopnea index (AHI) > 5, use of CPAP for sleep apnea, periodic leg movement index (PLMI) > 15, and abnormalities in cardiac tests (ECG at rest and with exercise).

We defined TST as two consecutive PSG nights. Seven patients who slept less than 5 hours in each of the 2 consecutive PSG nights were allocated into the “TST < 5h” group (full PSG sleep time < 5 hours). Twenty-three primary insomnia patients who slept more than 5 hours in the two PSG nights were included in the “TST > 5h” group (full PSG sleep time > 5 hours). Subjective sleep quality assessment was performed using the Pittsburgh Sleep Quality Index (PSQI)¹⁵.

Two consecutive laboratory-based PSGs were recorded with a digital system device (S7000; Embla Systems, Thornton, CO) during the participants' habitual sleep time. Standard montage and criteria for scoring sleep stages were used¹⁶. Arousals, leg movements and respiratory events were scored according to the guidelines provided by the American Academy of Sleep Medicine¹⁷.

Fasting metabolic laboratory parameters were measured, including glucose, cortisol, insulin, adrenocorticotropic hormone (ACTH) and growth hormone (GH). Blood samples were collected when the patients awakened. HOMA-IR was calculated using fasting glucose and insulin parameters.

The body composition included lean and fat mass assessments obtained via plethysmography, which involves

the use of an electronic balance, a plethysmograph, a cylinder for calibration, and dedicated software. The density of the whole body was obtained by dividing the body weight by the body volume.

Descriptive analyses were applied to the subject characteristics and the collected data. The differences between the groups were compared using the Mann-Whitney U test for continuous variables and the chi-square test for frequencies. P values of ≤ 0.05 were considered significant. The statistical analyses were performed using the Statistical Package for Social Sciences (SPSS) version 17.0 for Windows (SPSS Inc., Chicago, Illinois). The Spearman's rank correlation coefficients were obtained by considering the PSG total sleep time, socio-demographic variables and blood parameters.

RESULTS

No significant differences were found with respect to socio-demographic variables between the two groups (TST > 5h and TST < 5h). The majority of both groups are women which coincide with the prevalence of insomnia that is more common in females. The body mass index (BMI) and body composition were also similar in both groups. Comparisons of the PSG variables showed lower sleep efficiency and higher sleep onset latency for the TST < 5h group ($p < 0.01$ and $p = 0.03$, respectively). The demographic and PSG results are detailed in Table 1. The PSQI score was significantly higher among the insomnia patients who slept less than 5 hours, indicating worse sleep quality in this group (10.8 ± 2.2 vs. 14.1 ± 1.0 , $p < 0.01$).

With regard to laboratory metabolic variables, patients who slept less than 5 hours had higher fasting glucose and cortisol levels than those who slept more than 5 hours ($p = 0.01$ and $p = 0.02$, respectively) (values are displayed in Table 2). No differences were found for the other variables. Fasting glucose, ACTH and cortisol levels demonstrated inverse correlation with the total sleep time ($r = -0.28$, $p = 0.16$; $r = -0.38$, $p = 0.03$; $r = -0.47$, $p < 0.01$, respectively).

DISCUSSION

We found that an objective sleep duration less than 5h was associated with increased glucose and cortisol levels and a decreased subjective sleep quality in chronic insomnia patients. Total sleep time was inversely correlated with glucose, cortisol and ACTH levels. Shorter sleep was not associated with differences in BMI and body composition in our sample. We excluded cases of sleep disorders related to increased HPA activity, such as sleep-disordered breathing.

To the best of our knowledge, this study was the first to analyze blood metabolic parameters related to HPA axis activity of non-diabetic middle-aged adults with chronic insomnia

Table 1. Demographic and polysomnography (PSG) variables.

Characteristics	TST > 5 hours (n = 23)	TST < 5 hours (n = 7)	p-value
Gender (M/F)	3/20	2/5	
Age (years)	44.90 ± 8.8	43.10 ± 9.1	0.74
BMI (kg/m ²)	24.50 ± 4.7	24.30 ± 2.80	0.78
% fat mass	30.60 ± 9.6	32.50 ± 11.90	0.58
% lean mass	69.40 ± 9.8	67.40 ± 11.90	0.62
Insomnia duration (months)	9.90 ± 7.0	13.90 ± 10.60	0.47
PSG N1 (%)	3.51 ± 1.89	4.24 ± 2.52	0.41
PSG N2 (%)	55.73 ± 8.35	60.28 ± 2.99	0.17
PSG N3 (%)	19.60 ± 6.30	19.10 ± 4.80	0.84
PSG REM (%)	20.79 ± 6.87	16.30 ± 3.60	0.11
PSG SOL (min)	12.17 ± 10.45	24.25 ± 11.15*	0.03
PSG REM Lat (min)	92.9 ± 44.00	130.70 ± 69.90	0.24
PSG TST (min)	355.31 ± 36.17	256.21 ± 49.83*	< 0.01
PSG SE (%)	84.30 ± 7.90	67.00 ± 15.30*	< 0.01
PSG WASO (min)	52.60 ± 28.80	90.10 ± 18.10	0.41
AI	45.19 ± 52.38	15.35 ± 14.42	0.15
AHI	7.27 ± 7.41	9.74 ± 11.50	0.50
PLM	1.99 ± 4.31	0.00 ± 0.00	0.23
SaO2 (%)	95.82 ± 1.31	95.40 ± 2.09	0.64

BMI: body mass index; PSG N1 (%): percentage of stage N1; PSG N2 (%): percentage of stage N2; PSG N3 (%): percentage of slow wave sleep (stage N3); PSG REM (%): percentage of REM stage; PSG SOL (min): sleep onset latency; PSG REM Lat (min): REM latency; PSG TST (min): total sleep time; PSG SE (%): sleep efficiency; PSG WASO (min): time to wake after sleep onset; AI: arousal index (per hour); AHI: apnea and hypopnea index (per hour); PLM: periodic leg movement (per hour); SaO2 (%): mean oxygen saturation during sleep.

disorder with objective short sleep duration as measured by 2 consecutive PSGs. The HPA axis plays a role in the glucose metabolism impairment observed in insomnia as determined by objective and subjective criteria¹⁸. Objective short sleep duration is associated with physiological hyper-arousal in insomnia patients^{19,20}. Chronic stress system activity is related to increased cortisol levels²¹. Persistent sleep restriction may lead to insulin resistance and an increased risk of diabetes over time^{22,23}. Our findings confirm this hypothesis in part. Insulin and HOMA-IR did not differ between the groups.

Previous studies have examined the concept of objective short sleep duration based on only one PSG night²⁴. Although we have used data from more than one PSG night to classify short sleep duration, we still acknowledge that this data may not fully represent the sleep habits of subjects. The small sample size, mostly in the TST < 5 h group, the absence of a group of “good sleepers”, and the cross-sectional design limit the magnitude of our conclusions and causality inferences in the directions of the associations. As an example, the ACTH

Table 2. Blood parameters.

Variables	TST > 5 hours (n = 23)	TST < 5 hours (n = 7)	p-value
Fasting glucose (mg/dL)	95.21 ± 6.80	102.28 ± 4.50*	0.01
Cortisol (µg/dL)	12.75 ± 4.70	17.20 ± 2.80*	0.02
Insulin (µIU/mL)	7.41 ± 4.10	9.07 ± 6.30	0.73
HOMA IR	1.78 ± 1.07	2.31 ± 1.68	0.32
ACTH (pg/mL)	21.63 ± 21.20	73.21 ± 14.30	0.32
GH (ng/mL)	10.70 ± 28.60	16.37 ± 37.40	0.67

*p < 0.05, Mann-Whitney U test.

and insulin measurements presented a non-significant increasing trend in the insomnia group with short sleep duration. This result may be due to the low number of participants in this pilot study, which possibly underpowered the magnitude of the differences found between groups. More precise measurements of glucose metabolism, insulin sensitivity and HPA axis feedback control than those used in this study are also necessary to confirm our findings.

Furthermore, treating TST as a continuous variable for a secondary analysis demonstrated that fasting glucose, cortisol and ACTH levels displayed a fair inverse correlation with TST. These results favor the hypothesis that decreased sleep duration is related to changes in the HPA axis. Once chronic, this neuroendocrine pattern is a potential risk factor for diabetes, obesity and cardiovascular disease²⁵.

Keckels et al. found no association between insomnia and impaired glucose metabolism. However, the mean TST in the insomnia group was greater than 5h, and no sub-group analysis was performed to compare TST below and above 5h²⁶. In fact, an objective sleep duration of less than 5 h is necessary to increase the risk of diabetes^{8,27}. The severity of sleep disturbance is a key component in metabolic control, as only severe sleep apnea is clearly related to the risk of impaired glucose metabolism²⁸.

In conclusion, objective sleep duration of less than 5h in chronic insomnia disorder patients was associated with hormonal and metabolic measurements that indicated changes in HPA axis activity. Because insomnia is a chronic condition and our sample was composed of middle-aged adults, long-term preventive strategies targeting the morbidity and mortality related to poor sleep and its potential metabolic consequences may be effective. Insomnia disorder is a heterogeneous condition, and specific subtypes, such as insomnia with objective short sleep duration, require further investigation with respect to potential clinical outcomes and effective interventions.
