Abstract

Plants have the ability to recognize and respond to a multitude of pathogens, resulting in a massive reprogramming of the plant to activate defense responses including Resistance (*R*) and Pathogenesis-Related (*PR*) genes. Abiotic stresses can also activate *PR* genes and enhance pathogen resistance, representing valuable genes for breeding purposes. The present work offers an overview of soybean *R* and *PR* genes present in the GENOSOJA (Brazilian Soybean Genome Consortium) platform, regarding their structure, abundance, evolution and role in the plant-pathogen metabolic pathway, as compared with *Medicago* and *Arabidopsis*. Searches revealed 3,065 *R* candidates (756 in Soybean, 1,142 in *Medicago* and 1,167 in *Arabidopsis*), and *PR* candidates matching to 1,261 sequences (310, 585 and 366 for the three species, respectively). The identified transcripts were also evaluated regarding their expression pattern in 65 libraries, showing prevalence in seeds and developing tissues. Upon consulting the SuperSAGE libraries, 1,072 *R* and 481 *PR* tags were identified in association with the different libraries. Multiple alignments were generated for *Xa21* and *PR-2* genes, allowing inferences about their evolution. The results revealed interesting insights regarding the variability and complexity of defense genes in soybean, as compared with *Medicago* and *Arabidopsis*.

Key words: pathogen response, biotic stress, bioinformatics, *Glycine max*, *Medicago truncatula*.

Introduction

In order to prevent the effects of pathogen attack, plants evolved the ability to recognize the threat and struggle against the invader as well as trigger an effective response (Bolton, 2009). One of the most important steps of this complex response lies in the detection of pathogen invaders by the plant, a step where *R* (Resistance) genes play a crucial role. This sensing involves the recognition of a pathogen gene product called avirulence (*avr*) factor by a correspondent *R* gene. The plant will be resistant and the pathogen growth and establishment will be impaired when both *avr* and *R* genes are compatible, leading to the so-

called Hypersensitive Response (HR) that triggers diverse responses, including local cell death to impair spreading of the pathogen (Bonas and Anckerveken, 1999). Besides this local reaction, the HR activates a signal cascade – including hormones and *PR* (Pathogen Related) genes, among others – that are able to establish resistance against a spectrum of different pathogen classes, this corroborating observations made at the beginning of the last century that plants, as well as animals (Benko-Iseppon *et al.*, 2010), may be immunized against the attack of a given pathogen after infection by another pathogen (Chester, 1933).

Besides a local reaction, plants may also display the Systemic Acquired Resistance (SAR). The SAR pathway is also common in many non-compatible plant-pathogen interactions (Nurnberg and Brunner, 2002). As soon as the pathogenic agent is detected, the plant induces a complex set of signal molecules able to activate defense proteins that

may have a direct antimicrobial effect, as in the case of Pathogenesis-Related (*PR*) genes (Durrant and Dong, 2004). Alternatively, they may induce the production of secondary metabolites that impair pathogen movement or growth within the plant tissues (Sparla *et al.*, 2004).

Resistance genes are generally classified into five different groups or classes, defined according to their conserved domains (CD) (Bent, 1996; Hammond-Kosack and Jones, 1997; Ellis and Jones, 2000). The first class is represented by the *HMI* gene of maize that encodes a reductase able to inactivate toxins produced by the fungus *Helminthosporium carbonum* (Joahal and Briggs, 1992). It is the only *R* gene class where conserved domains are absent. A second class is represented by the *Pto* gene from tomato that confers resistance against the bacterium *Pseudomonas syringae* pv. *tomato*. It is characterized by a serine/threonine-kinase (ser/thre-kinase) domain, able to interact with the *avrPto* gene (Tang *et al.*, 1999). This gene was also identified in other plants, such as *Arabidopsis thaliana*, *Phaseolus vulgaris* (Melotto *et al.*, 2004), eucalyptus (Barbosa-da-Silva *et al.*, 2005) and sugarcane (Wanderley-Nogueira *et al.*, 2007).

The third class is represented by genes bearing two domains, viz. LRR (*Leucine Rich Repeats*) and NBS (*Nucleotide Binding Site*) (Liu *et al.*, 2004). This is the case of the *Rpm1* and *Rps2* genes from *A. thaliana*, the *N* gene from tobacco, *L6* from flax, *Prf* from tomato and *Rpg1* from soybean also found in common bean and faba bean (Mindrinos *et al.*, 1994; Lawrence *et al.*, 1995; Salmeron *et al.*, 1996; Ashfield *et al.*, 2003). The fourth *R* gene class encodes a membrane-anchored protein composed of an extracellular LRR domain, a transmembrane region and a short intracellular tail in the C terminal. The *Cf* gene from tomato is an example of this class, conferring resistance against *Cladosporium fulvum* (Dixon *et al.*, 1996).

The *Xa21* gene from rice confers resistance to the bacteria *Xanthomonas oryzae* pv. *oryzae* and is a representative of the fifth class (Song *et al.*, 1995; Wang *et al.*, 1995). This gene encodes an extracellular LRR domain (similar to the *Cf* gene), as well as a ser/thre-kinase domain (similar to the *Pto* gene), suggesting an evolutionary connection among different classes in the genesis of plant *R* genes (Song *et al.*, 1997).

PR proteins comprise pathogen-induced proteins that are routinely classified into 17 families based on their biochemical and molecular biological properties, from *PR-1* to *PR-17* (van-Loon *et al.*, 2006). Similarities among sequences and serological or immunological properties form the basis of their classification (van-Loon *et al.*, 1999). Although most *PR* proteins are known to have antifungal activities, their active molecular mechanisms are not well understood except for *PR-2* (β -glucanases) and *PR3* (chitinases) (Kitajima and Sato, 1999). *PR1* is the most abundantly accumulated protein after pathogen infection and its genes have been cloned in many plants, such as to-

bacco (Gaffney *et al.*, 1993), *A. thaliana* (Metzler *et al.*, 1991), tomato (Tornero *et al.*, 1997) and apple. Although its phytochemical functions are unknown in all these species, this gene class is nonetheless considered to be a typical SAR marker (Bonasera *et al.*, 2006). *PR-5* is a thaumatin-like protein with high antifungal activity, being also expressed under cold stress in overwintering monocots where it exhibits antifreeze activities (Hon *et al.*, 1995, Atici and Nalbantolu, 2003, Griffith and Yaish, 2004). Other families like *PR-8* (Glycosyl hydrolase), *PR-9* (secretory peroxidase), *PR-14* (lipid transfer proteins), *PR-15* (oxalate oxidase) and *PR-17* (basic secretory proteins) (Nanda *et al.*, 2010) have been well studied and are believed to be involved in plant defense responses, although their molecular mechanisms have yet to be determined (Bolton, 2009). Most *PR* genes are expressed at a basal level under normal growth conditions, but are rapidly induced after pathogen infection. It is worthy of note that several *PR* genes are also regulated during development, leaf senescence and pollen maturation, as well as by environmental factors, such as osmotic, cold and light stress (Zeier *et al.*, 2004).

Soybean (*Glycine max*) is a globally important crop, providing oil and at least twice as much protein per acre as any other major grain (Libault *et al.*, 2010). Economically, soybean is the most valuable source of protein and edible oil crop in the world and serves as a model for seed and other developmental processes (Cannon *et al.*, 2009).

The present evaluation offers an overview of the main available sequences regarding plant-pathogen interaction of the *R* and *PR* classes in the soybean transcriptome, here compared with data available from *Arabidopsis* and *Medicago*, providing insights on the expression of such sequences in different tissues and inferring as to how these genes may have behaved over the course of evolution.

Material and Methods

Search and screening for *R* and *PR* genes in soybean, *Medicago* and *Arabidopsis* databases

For this purpose 59 proteins that play important roles in plant defense response were selected as seed sequences. The selected protein sequences were related to the 42 *R* and 17 *PR* gene classes described above. The *R* genes were previously compiled by Barbosa-da-Silva *et al.* (2005) and Wanderley-Nogueira *et al.* (2007), and *PR* seed sequences are available in Table S1 (Supplementary Material). All 59 seed sequences regarded full cDNAs that were obtained from the NCBI database and conceptually translated to improve search strategies.

For the identification of these gene analogs in soybean, *Medicago* and *Arabidopsis* transcriptomes, tBLASTx alignments were carried out against three platforms: GENOSOJA (The Brazilian Soybean Genome Consortium), TIGR (The Institute for Genomic Research) and

TAIR (The Arabidopsis Information Resource), using $1e^{-05}$ as the cut-off value.

Obtained clusters were annotated and analyzed for score, e-values, sequence size and presence of conserved domains, as shown in Table 1. For this purpose all clusters were translated using the TRANSLATE tool of Expasy and screened for conserved motifs with the aid of the rps-BLAST CD-search tool (Altschul *et al.*, 1990). The best match for each gene in each studied species was submitted to a BLASTx alignment in NCBI GenBank in an effort to confirm their putative function.

In a second manual analysis redundancies, *i.e.* clusters that matched more than one gene due to common domains, were eliminated. For this purpose, clusters matching each query sequence were annotated on a local database (called 'non-redundant').

The third step of the analysis aimed at comparing the number of R and PR candidate sequences obtained after the tBLASTn searches against the soybean, *Arabidopsis* and *Medicago* databases by direct counting of non-redundant clusters for each one of the 59 genes studied.

Phylogenetic analysis

Aiming to analyze the relationships among these genes, some R and PR gene candidates were selected from all three studied species for an evolutionary analysis using the maximum parsimony method and bootstrap function with 5,000 replicates. For this purpose CLUSTALx alignments were submitted to the program MEGA (Molecular

Evolutionary Genetic Analysis), Version 4 for Windows (Tamura *et al.*, 2007).

Studying syntenic regions among the soybean and *Medicago* genomes

Best matches for all selected soybean genes were aligned against the *M. truncatula* pseudogenome aiming to anchor the 59 soybean sequences in virtual chromosomes through the CVit-BLAST procedure implemented in the *Medicago* sequencing resource website. BLAST algorithm parameters (score, e-value and percentage of identity) were adjusted to infer about the position of soybean sequences along the *Medicago* virtual chromosomes.

In silico expression assay based on GENOSOJA EST sequences

A preliminary analysis of the prevalence regarding the 59 genes in the soybean libraries was verified by direct correlation of the read frequencies of each cluster in various GENOSOJA cDNA libraries. Information regarding the 65 libraries that constitute the GENOSOJA database is available on The Soybean Genome Project Website. For practical purposes we combined some libraries that comprised different stages of the same tissue/organ (for example, B01 and B02 are here referred to as "B"), resulting in a total of 16 libraries (**B**: vegetable buds of field grown plants; **C**: cotyledons; **EN**: endosperm; **EP**: epicotyls; **F**: flowers; **H**: hypocotyls; **LV**: leaves; **R**: roots; **SH**: germination shoots; **ST**: stems; **SO**: somatic embryos; **SC**: soybean submitted

to drought; **LI**: leaves infected with Asian rust; **MJ**: soybean submitted to *Meloidogyne javanica*; **SD**: seeds and **UK**: unknown). To generate an overall picture of selected R and PR gene expression patterns in soybean, a hierarchical clustering approach (Eisen *et al.*, 1998) was applied using normalized data and a graphic representation constructed with the aid of the CLUSTER program. Dendrograms including both axes (using the weighted pair-group for each cluster and library) were generated with aid of the TreeView program (Page, 1996). In these graphics, light yellow means no expression and red indicates all degrees of expression.

In silico expression assay based on the GENOSOJA SuperSAGE libraries

R and PR candidates were also used to screen the six SuperSAGE libraries generated by the GENOSOJA consortium. For the drought experiment, four libraries were generated using roots of two contrasting soybean genotypes, viz. Embrapa-48 (tolerant) and BR-16 cultivar (susceptible), both submitted to dehydration in the dark for 25 up to 150 min (all times bulked together), as compared with non-stressed controls. The other stressed library was generated using leaves of the resistant accession PI561356 inoculated with rust fungus and collected 12, 24 and 48 h post inoculation. For the composition of the pathogen-stressed library, equimolar amounts of the three inoculation times were used, as compared with the negative, non-inoculated control of the same genotype. The libraries were constructed at GenXPro GmbH (Frankfurt, Germany), essentially as described by Matsumura *et al.* (2008), and were subsequently sequenced via a SOLEXA platform.

Aiming to perform an overview of the GENOSOJA SuperSAGE data associated with R and PR genes, SuperSAGE tags were submitted to a BLASTn (maximum e-value $1e^{-05}$) against the database generated from three comparisons of the six available libraries (1-Embrapa-48, drought tolerant stressed vs. negative control; 2- BR-16, drought susceptible stressed vs. negative control; 3- PI561356 fungus resistant stressed vs. negative control). Each SuperSAGE tag was annotated considering the respective library comparison and also the respective aligned ESTs.

Results

Description and distribution of R and PR genes in soybean, *Medicago* and *Arabidopsis*

The tBLASTn alignment against the soybean transcriptome using the 59 known R and PR gene probes returned 1,066 non-redundant sequences from the contigs and singlets deposited in the GENOSOJA database. Among them, 700 represented contigs and 366 singlets, which together encompassed 26,653 reads. Regarding the tBLASTn searches in the *Medicago* transcriptome, a total

of 1,727 sequences were positive matches. In *Arabidopsis*, 1,533 sequences returned matches after the same procedure.

A screening of R and PR genes in these three species resulted in the identification of 4,326 candidates, of which 3,065 were R and 1,261 PR gene candidates. A graphical representation regarding the prevalence of these sequences and how they are distributed among the soybean, *Medicago* and *Arabidopsis* transcriptomes is shown in Figure 1.

After analyzing all results it was observed that only one PR (PR-13) and two R genes (L6 and M) were absent from the soybean transcriptome, while all the other 56 genes presented positive results in the tBLASTn searches. The same was denoted in the *Medicago* tBLASTn results for these three genes. Also in *Arabidopsis* no matches could be found for the two R genes L6 and M, but four candidate sequences could be identified for the PR-13 class, as shown in Table 1. A comparison of the distribution of non-redundant sequences in the three species revealed that the NBS-LRR family was the most frequent one in all cases, while the LRR-kinase class was the least represented in all studied organisms (Figure 2). Moreover, it was observed that while *Arabidopsis* presented a higher number of R gene candidates, *Medicago* matched the high number of PR genes. In both cases, soybean presented the lowest number of matches (Figure 3A).

The three most represented R and PR genes in all species were the same, with *Xa21*, *EFR* and *Pti6* representing R genes and PR-2, PR-7 and PR-9 representing PR genes.

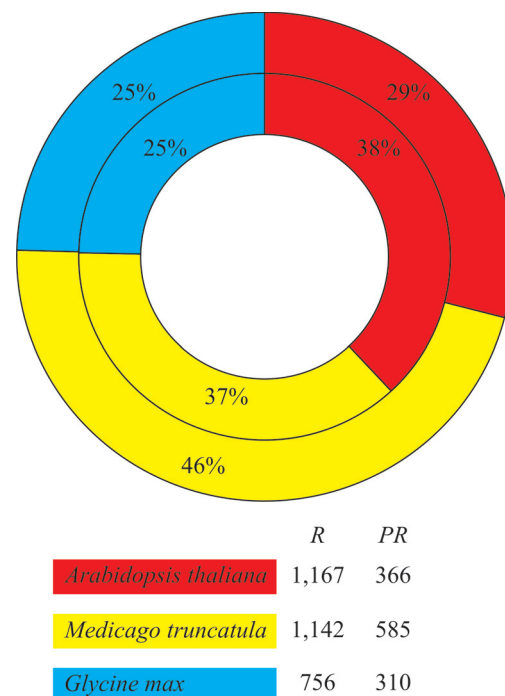

Figure 1 - R and PR genes encountered in soybean, *Arabidopsis* and *Medicago* transcriptomes. R genes are represented in the outer circle and PR genes in the inner circle for each species.

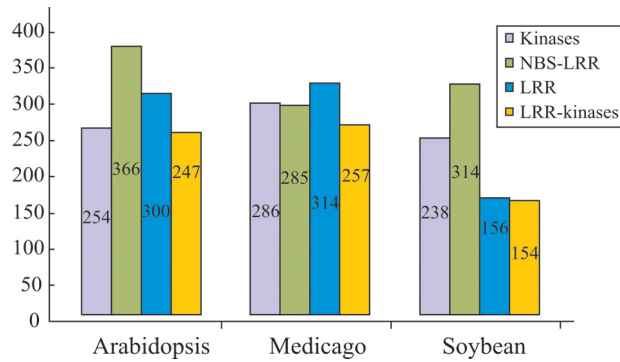

Figure 2 - Distribution of *R* gene families in soybean, *Arabidopsis* and *Medicago* in the four main *R* gene categories, considering their conserved domains. Column numbers correspond to the amount of non-redundant sequences for each class.

Figure 3 - Distribution of *R* and *PR* genes in soybean, *Medicago* and *Arabidopsis* (A). Distribution of *Xa21* and *PR-2* in soybean, *Medicago* and *Arabidopsis* (B). Numbers of matches for each gene category are shown inside the columns.

Due to this abundance, both *Xa21* and the *PR-2* genes were selected for the construction of a dendrogram and expression analysis. Matching of *Xa21* and *PR-2* candidates in soybean, *Medicago* and *Arabidopsis* did not follow a regular distribution pattern, since soybean presented fewer matches for both genes, and most of the *Xa21* candidate sequences were found in *Medicago*, whereas most *PR-2* candidates were found in *Arabidopsis* (Figure 3B).

Among the 310 *PR* genes of soybean only 40 matched with more than one seed sequence, all the others being exclu-

sive to a given *PR* gene family. On the other hand, almost all *R* genes matched sequences that aligned with more than one probe, requiring manual sorting. Exceptions occurred only with respect to *RAR*, *RIN*, *P*, *WRKY29*, and *Xa21*, which aligned in most cases with exclusive sequences.

Phylogenetic analysis of *Xa21* and *PR-2* genes

Dendrograms generated for *Xa21* and *PR-2* genes using the soybean sequences and orthologs clearly divided dicots and monocots into distinct clades (Figure 4). In the *Xa21* analysis, the fern *Selaginella moellendorffii* was placed in a basal position from which the two branches representing monocots and dicots emerged (Figure 4A). The monocots group included members of the Poaceae family in one branch, with a bootstrap CI of 95%, associated in the same branch with the palm *Elaeis guineensis*. Regarding the dicot group, it was observed that both Fabaceae members (*G. max* and *M. truncatula*) were positioned together, while the other branch included members of the suborder Eurosidae I (*Vitis vinifera* and *Ricinus communis*), together with *A. thaliana*, a member of the Eurosidae II suborder.

Considering the *PR-2* dendrogram (Figure 4B), the grasses (Poaceae represented by rice and maize) occupied a basal position, from which a clade containing two monocots, ginger (*Zingiber officinale*) and banana (*Musa paradisiaca*), emerged. Moreover, a large clade containing all dicots was split into two subclades that behaved as merophyletic groups. For example, tobacco (*Nicotiana tabacum*) and coffee (*Coffea arabica*), members of the Asterid order, remained together, but potato (*Solanum tuberosum*) of the same order was positioned on another branch. Soybean and *Medicago* were also positioned in separate subclades.

Expression pattern of *R* (*Xa21*) and *PR* (*PR-2*) genes in the soybean transcriptome

From the 26,653 reads identified, an *in silico* expression assay was carried out considering transcripts from both genes *Xa21* (2,980 reads) and *PR-2* (1,099 reads). This allowed identifying their prevalence and normalizing their distribution among the tissues and conditions represented in the 65 different libraries. Graphic illustrations of these comparisons are available as Figures S1 and S2 (Supplementary Material).

The analysis of their expression pattern in soybean, obtained from normalized data, revealed that all libraries presented almost the same number of reads. The most representative library was from seed tissues (SD), presenting 10% of the identified reads. Expression in tissues from leaves (LV), roots (R) and flowers (F) presented similar expression, representing 9% of all reads in each tissue. The remaining tissues also presented significant expression (ranging from 5% to 8%), except in the case of libraries made from tissues submitted to the nematode *Meloidogyne javanica* (MJ), where no reads were identified.

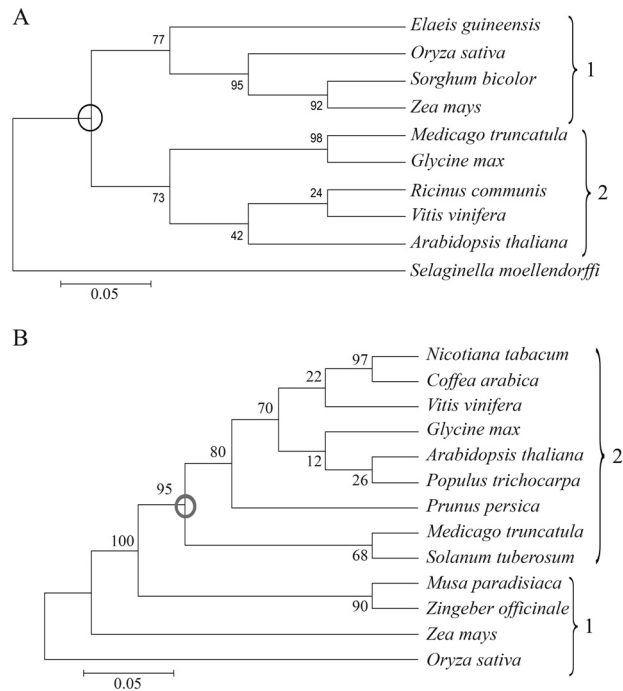

Figure 4 - Dendrograms generated after maximum parsimony analysis showing the relationships among selected plant species considering sequences of (A) *Xa21* and (B) *PR-2*. Keys in (1) represent monocots and in (2) dicots. *Xa21*: the circle on the root of A shows the divergence point between monocots and dicots. *PR-2*: the circle on the root of B shows an ancestor with a sympleiomorphic character. Numbers at the base of the branches denote bootstrap values and the bar represents the evolutionary scale.

Expression considering the SuperSAGE libraries

BLASTn results revealed that 944 soybean EST candidates aligned with 1,553 SuperSAGE tags when considering a cut-off value of $\leq e^{-5}$. Among all tags, 1,072 aligned with the *R* gene candidates from different classes, with emphasis on the NBS-LRR class. Additionally, 481 tags aligned with *PR* gene candidates, most of them with the *PR-9* secretory peroxidase family (Figure 5). Data concerning sequence-tag association are available as supplementary material (Tables S2, S3 and S4). The best results were obtained for comparison 1 (BR-16, drought susceptible stressed vs. negative control), which matched 613 non-redundant tags, while 465 were found for comparison 2 (Embrapa-48, drought tolerant stressed vs. negative control), and for comparison 3 (PI561356 fungus resistant stressed vs. negative control) 475 SuperTags were represented (Figure 5). It is noteworthy that many tags matched in more than one comparison.

Anchoring soybean *R* and *PR* genes in *Medicago* virtual chromosomes

The alignment of 59 soybean genes against the *Medicago* virtual chromosomes revealed 1,253 sites in all nine chromosomes, also including sub-telomeric regions

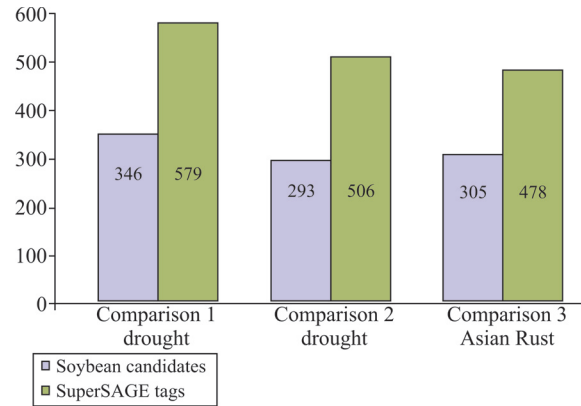

Figure 5 - Number of SuperSAGE tags matching soybean *R* and *PR* gene candidates from three different comparisons among the six libraries: 1-Embrapa-48, drought tolerant stressed vs. negative control; 2- BR-16, drought susceptible stressed vs. negative control; 3- PI561356 fungus resistant stressed with *Phakopsora pachyrhizi* vs. negative control.

(Figure 6). 58 genes presented similarities with distinct segments in the same chromosome or appeared twice in distinct chromosomes. Only the *PR-1* sequence anchored in an exclusive chromosome (2).

The highest number of anchored genes was found in chromosome 8, matching 32 of the 59 genes in 85 sites. On the other hand, chromosome 6 presented the lowest number of anchored genes (12). Nonetheless, this chromosome presented the highest number of duplications, matching 228 sites, most of them in tandem positions. Such tandem repetitions could be also observed in three sites of chromosome 3. The lowest gene density was observed in the long arm of chromosome 3. Syntenic regions were evident in chromosomes 2 and 4 (Figure 6).

Several sequences clustered along the genome, with some chromosomes rich in resistance genes, especially chromosomes 2, 7, 8 and 9, with at least four distinct genes in very close positions. These blocks of genes always matched *R* genes, while *PR* genes generally appeared in the same chromosomes in distinct sites.

Discussion

The 1,066 soybean sequences resulting from tBLASTx alignments confirmed the excellent coverage that the existing GENOSOJA databank comprises, including the most important representatives from different gene families.

Legumes are plants known to be able to withstand many kinds of stresses, including rapid climate changes, drought tolerance, exposure to diseases and pests, water logging and flooding (Cannon *et al.*, 2009), which could explain the higher number of *PR* genes encountered in *Medicago* in comparison to *Arabidopsis*, since these families of genes can be activated by different kinds of biotic or abiotic stress (Glombitza *et al.*, 2004). The low number of *R* and *PR* gene candidates found in soybean is curious when

Figure 6 - Graphic representation of soybean *R* and *PR* sequences positioned on *Medicago truncatula* chromosomes (MtChr) with the aid of the CVit-BLAST resource available at the website <http://www.medicago.org/>. Arrows indicate genes that appear in tandem repetitions.

compared to *Arabidopsis* and *Medicago*, since these have smaller genomes (157 Mb and 583 Mb respectively) than that of *G. max* (1,115 Mb). This may be due to the analyzed sample, which was restricted to expressed sequence tags, whereas the databases of both *Arabidopsis* and *Medicago* are larger. Previous studies on legumes showed that despite the relatively large difference in genome sizes of soybean and *Medicago*, gene densities are similar, indicating that a given *Medicago* region is likely to correspond well with two soybean regions (Mudge *et al.*, 2005). This leads us to believe that additional expression assays in soybean may reveal important genes that are expressed under very specific conditions.

The number of soybean clusters that aligned with more than one *R* gene seed sequence is not surprising. Similar results were observed in previous studies regarding *R* genes of eucalyptus (Barbosa-da-Silva *et al.*, 2005) and sugarcane (Wanderley-Nogueira *et al.*, 2007). This occurs due to the common domains shared by *R* genes, as for example the LRR domain that is present in the LRR, NBS-LRR and LRR-kinase gene families, facilitating alignments with more than one gene. This is rarer when considering *PR* gene categories that are more distinct in structure and function (Kitajima and Sato, 1999), as also observed herein. A higher number of sequences matching NBS-LRR families, when compared to other classes, was also reported by Barbosa-da-Silva *et al.* (2005) and Wanderley-Nogueira *et*

al. (2007), confirming the general observation that most *R* genes are members of this class.

Dendrograms generated from these data revealed a similar picture in both gene classes selected (*Xa21* and *PR-2*). In the case of *Xa21*, the positioning of *Selaginella moellendorffii* as an outgroup was expected, since this species figures as a member of an ancient vascular plant lineage that first appeared 400 million years ago, and thus represents a basal node on the plant evolutionary tree (Weng *et al.*, 2008). The analysis of the *Xa21* orthologs from different species reflected their relationship according to classic taxonomy. Liliopsida class (monocots) appeared as a monophyletic group uniting on the same branch *Oryza sativa*, *Zea mays* and *Sorghum bicolor*, which are all annual cereal grains of the Poaceae family, while the palm *Elaeis guineensis* (Arecaceae) was positioned on another branch. Considering the Magnoliopsida (dicots), the same occurred, since *Medicago* and soybean, both legumes and members of Fabaceae, appeared in a subclade, separated from the remaining species. *R* genes are considered fast evolving, due to their co-evolution with specific pathogens (Michelmore and Meyers, 1998). In the case of *Xa21* the most polymorphic region is its extracellular LRR domain, which is responsible for pathogen specificity (Ellis *et al.*, 2000), defining the relationships of the dendrogram presented here.

The *PR-2* dendrogram topology showed two main clades, as expected, monocots and dicots. The grouping of monocots followed the taxonomic relationship, segregating *Musa* and *Zingiber* (Zingiberales) from *Oryza* and *Zea* (Poaceae). It was possible to identify that a symplesiomorphic character united all dicots, reflecting their common origin. Moreover, considering the Magnoliopsida group, the evolutionary model of the *PR-2* class seemed to follow a synapomorphic pattern, leading to their diversification in different groups comprising families and orders, this probably reflecting divergent processes regarding this *PR* gene.

The studied organisms presented different centers of origin, habitats and cycles of life, as well as tolerance, resistance and sensitivity to diverse kinds of biotic and abiotic stresses. Nonetheless, from an overall perspective and considering the position of different species in the dendrograms, it is evident that both *Xa21* and *PR-2* pathways genes were present in a common ancestor of the angiosperms, since they appear relatively conserved in different plant groups.

Many *PR* genes are constitutively expressed in given plant tissues (Velazhahan and Muthukrishnan, 2003; Liu *et al.*, 2004), suggesting a link between biotic and abiotic stresses and indicating that at least some members of the *PR* proteins play important roles in plant development, besides their role in defense responses. This fact may explain why the expression of *PR-2* gene can be observed at a basal level in almost all tissues, as seen when considering their frequencies in the soybean libraries.

Studies carried out by Li *et al.* (2008) and Libault *et al.* (2010) revealed consistent differences in gene expression patterns among diverse tissues, especially between roots and aerial tissues, but also revealed similarities between expression levels in tissues such as flowers and leaves, corroborating our results. The most represented library was for seeds, including different development stages, which is not surprising, since previous evaluations also revealed that the soybean grain contained the vast majorities of expressed genes and regulatory sequences in the plant (Cannon *et al.*, 2009). In the case of the *PR-2* protein, it is interesting to note that previous evaluations carried out by Leubner-Metzger (2005) in tobacco suggest that this gene could play a role in seed germination. Furthermore, the expression of both genes was also increased in leaves, roots and flowers, confirming their prevalence in developing tissues.

As mentioned above, abiotic stress is able to trigger diverse plant responses. After an initial massive distribution of energy triggered by stress, a wide array of defense mechanisms is activated by *R* genes, inducing a signal cascade and increased *PR* gene transcription (Vergne *et al.*, 2010). This may justify the considerable amount of soybean SuperSAGE tags related to these genes among the three comparisons considered, with considerable represen-

tation in both biotic and abiotic (drought) conditions, as well as in the negative controls, with many tags represented in more than one treatment. The high number of tags that matched with BR-16 drought susceptible library vs. control could be explained by the ability of the plant to continue expressing genes related to systemic acquired resistance as a consequence of contact with any kind of previous stress, a crosstalk previously reported for other plants (Durrant and Dong, 2004; Kido *et al.*, 2011). Comparing the distribution between *R* and *PR* genes, both were representative with 1,072 tags matching *R* genes and 481 tags matching *PR* candidates, indicating that additional analytical efforts regarding the SuperSAGE candidates will reveal not only associations with specific situations, but also allelic differences important in the definition of biotic and abiotic stress responses.

Flowering plants originated approximately 200 million years ago (Wilkstrom *et al.*, 2001) and subsequently diverged into several lineages. Legumes are an old family believed to have originated approximately 54 Mya (Lavin *et al.*, 2005). Soybean and other papilionoid legumes show evidence of an older shared duplication and probably soybean underwent polyploidy 13 Mya (Shoemaker *et al.*, 2006). These duplications are widely evident, both in number of similar duplicated genes and in large areas of synteny between chromosomal regions. Previous evidence indicates extensive similarities in gene densities and distribution among soybean and *Medicago*, inferring that a given *Medicago* region is likely to correspond well with two soybean regions (Mudge *et al.*, 2005). This evidence suggests that *Medicago* could represent “a simplified draft” of the soybean gene distribution, making an evaluation regarding *R* and *PR* soybean ortholog distribution in this crop most desirable. Hence, it is not surprising that all identified soybean *R* and *PR* transcripts appeared anchored in 1,253 sites in all segments of *Medicago* virtual chromosomes.

The rich *R* gene regions found in chromosomes 2, 7, 8 and 9 confirm previous observations that most resistance genes reside in clusters (Kanazin *et al.*, 1996), as reported in maize (Dinesh-Kumar *et al.*, 1995), lettuce (Maisonneuve *et al.*, 1994), oat (Rayapati *et al.*, 1994) and flax (Ellis *et al.*, 1995). The formation of gene clusters is in general associated with a common ancestor, and the diversification of these genes is the result of duplication processes followed by diversification due to pathogen or environmental pressure.

Clustering of *R* genes corroborates the existing theory that a common genetic mechanism involving duplication has been responsible for the evolution and diversification of this gene superfamily (Hulbert *et al.*, 2001). The four clusters presented similarities with distinct segments in the same chromosome, probably reflecting tandem gene duplication mechanisms. Such duplicated copies tend to diverge by acquiring additional mutations and may specialize or

optimize to play slightly different roles (Alberts *et al.*, 2002).

Regarding the duplicated segments considering the entire genome, 58 genes could be identified in at least two distinct chromosomes. Unlike tandem duplications, repetitions in distinct chromosomes resulted from events of duplication followed by translocations and sequence divergence, also allowing functional diversification (Wendell, 2000; Thiel *et al.*, 2009). There is also evidence that transposition outbreaks could be activated by severe environmental biotic or abiotic stress.

Still regarding the duplication event analysis, a large in tandem repetition was evident in both chromosomes 3 and 6, represented by the genes *Xa1/12* and *RRS1*, respectively. Previous reports suggested that once duplicated, genes in tandem repetitions may expand rapidly through events of unequal crossing over, since the character could confer advantage to the organism (Alberts *et al.*, 2002), in this case a higher diversity of genes associated with resistance and stress response. This evidence supports assumptions that future efforts regarding increased pathogen resistance may rely on biotechnological inferences that consider whole gene clusters naturally associated in neighboring positions, rather than isolated genes (Dafny-Yelin and Tzfira, 2007), as has been traditionally done.

In conclusion, the here identified sequences represent valuable resources for the soybean breeding program, allowing their use in biotechnological approaches, with emphasis on transgenes. They are also valuable for mapping purposes, considering the putative distribution here uncovered when considering available distribution of genes known from the *Medicago* genome.

Considering gene diversity revealed especially by the SuperSAGE approach, their association with specific responses to biotic or abiotic stress conditions may reveal important gene variants for germplasm screening in the search for new accessions useful for breeding purposes, especially in association with marker assisted selection (MAS), saving decades of laborious research.

Supplementary Material

The following online material is available for this article:

Figure S1 - *Xa21* expression profile in 16 different libraries from GENOSOJA.

Figure S2 - *PR-2* expression profile in 16 different libraries from GENOSOJA.

Table S1 - Accession number of reference *PR* genes used as seed sequences.

Table S2 - Number of SuperSAGE tags per comparison.

Table S3 - SuperSAGE tags that matched genes.

Table S4 - Number of tag repetitions in comparisons matching *R* and *PR* genes.

This material is available as part of the online article from <http://www.scielo.br/gmb>.

Table S2 - Number of SuperSAGE tags per comparison (stressed library *versus* negative control for each gene family) that aligned with soybean candidates. Comparisons regarded: (1) BR-16 (drought susceptible stressed plants *vs.* negative control); (2) Embrapa-48 (drought tolerant plants after stress *vs.* negative control), and (3) PI561356 (rust fungus resistant plants after stress *vs.* negative control).

Soybean Candidate	Library			Gene
	BR16 drought	Embrapa 48 drought	PI561356 Rust

Table S4 - Number of tag and of repetitions in all three comparisons matching *R* and *PR* genes. Comparisons regard: (1) Embrapa-48, drought tolerant stressed vs. negative control; (2) BR-16, drought susceptible stressed vs. negative control and (3) PI561356 fungus resistant stressed vs. negative control).
