

## Phenotypical characterization of *Candida* spp. isolated from crop of parrots (*Amazona* spp.)<sup>1</sup>

Renata G. Vieira<sup>2</sup> and Selene D. Acqua Coutinho<sup>2\*</sup>

**ABSTRACT.**- Renata G. Vieira R.G. & Acqua Coutinho S.D. 2009. **Phenotypical characterization of *Candida* spp. isolated from crop of parrots (*Amazona* spp.).** *Pesquisa Veterinária Brasileira* 29(6):452-456. Curso de Pós-Graduação em Imunopatologia Veterinária, Universidade Paulista, Rua Agariba 48, São Paulo, SP 05053-010, Brazil. E-mail: [selene@uol.com.br](mailto:selene@uol.com.br)

The purpose of this study was to characterize *Candida* isolates from crop of parrots. Forty baby parrots of genus *Amazona*, species *aestiva* and *amazonica* that were apprehended from wild animal traffic were used: 18 presented ingluvitis and 22 other alterations, but showing general debilitation. Samples were seeded on Sabouraud dextrose agar with chloramphenicol after be obtained by the introduction of urethral probe through the esophagus. Based on morphology and biochemical reactions (API 20C) *Candida* was confirmed; it was still searched the production of proteinase and phospholipase, virulence factors for *Candida* species. *Candida* spp. were isolated from 57.5% parrots, being 72.2% from birds with ingluvitis and 45.5% from without ones. Twenty-five strains of *Candida* were isolated, 60% and 40%, respectively from parrots with and without ingluvitis, and were speciated: 28% *C. humicola*, 24% *C. parapsilosis*, 20% *C. guilliermondii*, 20% *C. famata*, and 8% *C. albicans*. These results demonstrate that *C. albicans* is not the most frequent species isolated, and it is the first report that shows *C. guilliermondii*, *C. famata*, and *C. humicola* causing infection in parrots. Many isolates presented filamentation (76%), 100% produced proteinase and 68% phospholipase. The observation of *Candida* spp. producing virulence factors reinforce the pathogenic role of these yeasts in the cases studied.

INDEX TERMS: *Candida* spp., candidiasis, crop, ingluvitis, parrots, *Amazona* spp.

### RESUMO.- [Caracterização fenotípica de *Candida* spp. isoladas de Inglúvio de papagaios (*Amazona* spp.).] O

objetivo do presente trabalho foi caracterizar cepas de *Candida* spp. isoladas de Inglúvio de papagaios. Foram utilizados 40 papagaios do gênero *Amazona*, espécies *aestiva* e *amazonica*, apreendidos de tráfico de animais selvagens: 18 apresentavam ingluvite e 22 outras alterações, mas todos mostrando sinais de debilitação geral. Colheram-se as amostras clínicas através da introdução de sonda uretral no esôfago dos animais e estas foram semeadas em ágar Sabouraud dextrose acrescido de clo-ranfenicol. A identificação das espécies de *Candida* foi

baseada em características macro e micromorfológicas e comportamento bioquímico no kit API 20C; pesquisou-se ainda a produção das enzimas proteinase e fosfolipase. Isolou-se *Candida* spp. de 57,5% dos papagaios, sendo 72,2% de aves com ingluvite e 45,5% de aves com outras afecções. Isolaram-se 25 cepas de *Candida*, 60% e 40% respectivamente de animais com e sem ingluvite. As espécies isoladas foram: *C. humicola* (28%), *C. parapsilosis* (24%), *C. guilliermondii* (20%), *C. famata* (20%) e *C. albicans* (8%). Os resultados obtidos demonstram que *C. albicans* não é a espécie mais freqüentemente isolada e é a primeira vez que se relata *C. guilliermondii*, *C. famata* e *C. humicola* causando infecção em papagaios. A maioria dos isolados apresentou filamentação (76%) e produziu a enzima fosfolipase (68%) e todas as cepas produziram proteinase. O encontro de *Candida* spp., produzindo seus fatores de virulência, reforça o papel patogênico dessas leveduras nos casos estudados.

## INTRODUCTION

*Candida albicans* is yeast that can be present in the digestive, urinary and reproductive tracts of birds, and it is common to isolate few of these fungi from healthy animals (Mancianti et al. 2002). It may, however, be the cause of gastroenteropathies (Harrison 1986, Speer 1995, Kano et al. 2001, Schmidt et al. 2003). Candidiasis may occur as a primary or secondary infection, such as due to prolonged use of antibiotics, vitamin A deficiency, avian pox, trichomoniasis, chronic stress, malnutrition, and unsanitary conditions (Harrison 1986, Speer 1995, Schmidt et al. 2003, Godoy 2006).

Clinical signs of candidiasis depend on the site of infection, and the crop is the most commonly affected organ in young birds (Speer 1995, Lamberski 2003). Signs of crop infection include regurgitation, delay in crop emptying and crop dilatation, depression, anorexia and weight loss, emaciation, and growth impairment (Speer 1995, Lamberski 2003, Schmidt et al. 2003, Godoy 2006).

Host-parasite relationships depend on the balance between the virulence of the microorganism and defenses of the host. As for *Candida* sp., it is known that some deficiencies in the immune response are usually present for disease occurrence. However, some *Candida* strains are so virulent that they can cause infections in apparently healthy individuals. The ability to produce filaments, to adhere to epithelial surfaces and to secrete hydrolytic enzymes seems to be the most important virulence factor for *Candida* (Barret-Bee et al. 1985, Odds 1985, Dolan et al. 2004). In these situations, the incidence of candidiasis may increase, and the yeast presents characteristics of an actual opportunistic microorganism (Barret-Bee et al. 1985).

The occurrence of candidiasis is suspected when blastoconidia associated with pseudohyphae or true hyphae are found, once filamentation represents in vivo increase of pathogenicity (Barret-Bee et al. 1985, Koneman & Roberts 1990).

Many microorganisms produce hydrolytic enzymes that favor their pathogenicity. It has already been demonstrated that the secretion of enzymes is an important virulence factor for *C. albicans*, making easier its penetration into tissues (Price et al. 1982, Rùchel et al. 1982, Barret-Bee et al. 1985, Odds 1985, Dolan et al. 2004).

In humans, the ever growing number of fungal infections, mainly candidiasis, is strongly associated with concurrent immunosuppressing diseases, such as tumors and AIDS (Bodey et al. 2002, Costa et al. 2006). In poultry, this association has been observed by researchers with the description of candidiasis associated with coccidiosis in turkeys (Moretti et al. 2000). *Candida* spp. were also isolated from the lungs of pigeons that presented concomitant cryptococcosis (Bernardo et al. 1994) and from psittacines kept in captivity (Hinz et al. 2000) which is also

a stressful/debilitating condition for the animals (Lamberski 2003).

Studies have shown that the illegal trade and the loss of habitats are the main risk factors for the 90 endangered psittacine species in the world (IUCN 2008). From a total of 344 species known, 72 are found in Brazil, and 40% of them are rare and/or endangered (IUCN 2008). Therefore, studies that enable a better understanding of the diseases that affect these animals contribute for the management and survival of these species.

The objective of this study was to characterize phenotypically strains of *Candida* isolated from the crop of parrots of the genus *Amazona*, in order to better understand the role that these yeasts may play in the overall health of these birds.

## MATERIALS AND METHODS

### Selection of the population

Forty baby parrots of genus *Amazona*, species *aestiva* (Blue-fronted parrot, 29 animals) and *amazonica* (Orange-winged parrot, 11 animals), were used in this study. They were apprehended by forest police from illegal trade (Fig.1) and placed into a governmental recovery center. Eighteen birds presented clinical signs compatible with ingluvitis - delay in emptying the crop, regurgitation, depression, anorexia, emaciation, and diarrhea (Kano et al. 2001, Lamberski 2003, Schmidt et al. 2003). Although 22 of them did not present any signs of ingluvitis, they were so debilitated; some of them presented bone dislocations and/or fractures, chronic wounds and dyspnea due to transportation stress and overpopulation.

### Specimen collection

Samples were obtained from the crop using a sterile urethral probe nº 8 or 10 through the esophagus of the birds. Samples were transferred to sterile swabs, which were kept under refrigeration and sent to the laboratory within up to 24 h.

### Direct examination

Direct examination of the clinical samples was performed by means of a smear of the crop secretion on a slide, which

Fig.1. Babe parrots (*Amazona aestiva*) recently arrived in the recovery center, apprehended from illegal trade of wild animals.

was Gram-stained. Morphology and number of buds, and presence or absence of filamentation (germ tube, pseudohyphae and/or true hyphae) were searched (Koneman & Roberts 1990).

#### Isolation

Samples were cultured onto Petri dishes containing Sabouraud dextrose agar (Difco™) with chloramphenicol (100mg/L). Incubation was performed at 37°C for seven days.

#### Morphologic characterization

**Production of germ tube.** This technique was performed by means of suspension of the strain in a tube containing 0.5mL of sterile rabbit serum, followed by incubation at 37°C. After that, the suspension was placed on a glass slide covered with a cover slip, and examined every hour, for 4 hours, under a light microscope, in order to assess the production of germ tube (Koneman & Roberts 1990).

**Filamentation.** This test was performed on a sterile glass slide covered with rice agar<sup>3</sup> (Koneman & Roberts 1990). After solidification, one sample of the colony was streaked in parallel and equidistant lines on the surface of the agar, which was partially covered with a sterile cover slip. Incubation was performed in a humid chamber at 37°C for 24-48 h. Growth was observed under optical microscope, in order to assess the production of blastoconidia, chlamydoconidia, pseudohyphae, and true hyphae (Koneman & Roberts 1990).

#### Biochemical identification

Biochemical characterization to confirm genus and species was performed using kit API 20C AUX Bio-Mérieux (API®, Analytical Profile Index, BioMérieux SA, France).

#### Exoenzymes production

**Proteinase and phospholipase.** The production of proteinase and phospholipase was investigated by employing the techniques described for *C. albicans* (Price et al. 1982, Rùchel et al. 1982). For the production of proteinase (Prz) the readings were taken after 24, 48, and 72 h. For the production of phospholipase (Pz) the readings were done after 48, 72, 96 h and after 5, and 7 days. The formation of a halo (zone of precipitation) around the colony was considered to indicate enzyme production. The enzymatic activities (Prz and Pz i.e., activities of enzymes proteinase and phospholipase as noted above) were measured in terms of the ratio of colony diameter to the total diameter of colony plus the zone of precipitation (Price et al. 1982). Therefore, Pz = 1.00 would be a negative strain; Pz <1.00 and ≥0.64 would be a positive strain and Pz <0.64 would be a strongly positive strain for the production of the enzymes (Price et al. 1982).

#### Statistical analysis

Variance analysis tests were applied to compare *Candida* isolates in birds with and without ingluvitis; the rejection level of the null hypothesis was fixed at 0.05 or 5 % ( $p \leq 0.05$ ) (Zar 1996).

<sup>3</sup> Rice (20g) + water (1 L), to boil during 45 minutes; to pass the solution through a filter and to add bacteriological agar (2%); to place in an autoclave at 120°C for 15 minutes.

## RESULTS

### Selection of the population

*Candida* spp. were isolated from 23/40 (57.5%) parrots, being 13/18 (72.2%) from birds with clinical signs of ingluvitis and 10/22 (45.5%) from without ingluvitis; there was no significant differences in behavior between the isolates originating in infection of the crop or not. Twenty-five strains of the *Candida* spp. were isolated, 15/25 (60%) and 10/25 (40%), respectively from animals with and without ingluvitis, with no statistical differences between them. Therefore, in the other tests, a total of 25 strains of *Candida* were used.

### Morphologic characterization

**Direct examination.** The presence of round, oval and/or elongated yeast cells, with single or multiple buds was observed. In 11 out of 25 strains (44%), direct examination showed the presence of germ tube, pseudohyphae and/or true hyphae (Fig.2).

Fig.2. *Candida humicola* presenting filamentation in direct examination of crop specimen. Gram-stained, magnification 1,000x.

**Production of germ tube and filamentation.** It was observed that 19 out of 25 strains (76%) produced germ tube, pseudohyphae and/or true hyphae (Table 1), and 2 out of 25 (8%) produced chlamydoconidia (*C. albicans*).

### Biochemical characterization

Five species of genus *Candida* were identified, being 28% (7/25) *C. humicola*, 24% (6/25) *C. parapsilosis*, 20% (5/25) *C. guilliermondii*, 20% (5/25) *C. famata*, and 8% (2/25) *C. albicans*. The occurrence of mixed infection, caused by two different species, was observed in two animals (Table 1).

### Exoenzymes production

**Proteinase and phospholipase.** All strains strongly produced proteinase enzyme, after 72h, having mean value Prz = 0.28 (Table 1). Concerning phospholipase production, 17/25 (68%) strains produced that enzyme,

**Table 1. Phenotypical characterization of *Candida* strains isolated from crop of parrots (*Amazona aestiva* and *A. amazonica*)**

| Strain | Species             | Ingluvitis | Filamentation | <i>Candida</i> spp.      | Proteinase <sup>a</sup> | Phospholipase <sup>b</sup> |
|--------|---------------------|------------|---------------|--------------------------|-------------------------|----------------------------|
| 1a     | <i>A. aestiva</i>   | Presence   | Positive      | <i>C. parapsilosis</i>   | 0.24                    | 0.81                       |
| 1b     |                     |            | Positive      | <i>C. guilliermondii</i> | 0.28                    | 0.58                       |
| 2      | <i>A. aestiva</i>   | Presence   | Positive      | <i>C. albicans</i>       | 0.26                    | 1                          |

| 7b     |                     |            | Positive      | <i>C. guilliermondii</i> | 0.24                    | 0.61                       |
| 8      | <i>A. aestiva</i>   | Presence   | Positive      | <i>C. humicola</i>       | 0.18                    | 0.43                       |
| 9      | <i>A. aestiva</i>   | Presence   | Negative      | <i>C. famata</i>         | 0.45                    | 0.60                       |
| 10     | <i>A. aestiva</i>   | Presence   | Positive      | <i>C. parapsilosis</i>   | 0.31                    | 0.50                       |
| 11     | <i>A. aestiva</i>   | Presence   | Negative      | <i>C. parapsilosis</i>   | 0.22                    | 1                          |
| 12     | <i>A. aestiva</i>   | Presence   | Positive      | <i>C. parapsilosis</i>   | 0.22                    | 0.86                       |
| 13     | <i>A. amazonica</i> | Presence   | Positive      | <i>C. humicola</i>       | 0.31                    | 0.42                       |
| 14     | <i>A. aestiva</i>   | Absence    | Positive      | <i>C. parapsilosis</i>   | 0.31                    | 0.57                       |
| 15     | <i>A. aestiva</i>   | Absence    | Negative      | <i>C. famata</i>         | 0.18                    | 0.76                       |
| 16     | <i>A. amazonica</i> | Absence    | Positive      | <i>C. guilliermondii</i> | 0.27                    | 0.79                       |
| 17     | <i>A. aestiva</i>   | Absence    | Positive      | <i>C. humicola</i>       | 0.25                    | 0.71                       |
| 18     | <i>A. aestiva</i>   | Absence    | Negative      | <i>C. famata</i>         | 0.36                    | 1                          |
| 19     | <i>A. aestiva</i>   | Absence    | Negative      | <i>C. famata</i>         | 0.36                    | 1                          |
| 20     | <i>A. amazonica</i> | Absence    | Positive      | <i>C. humicola</i>       | 0.27                    | 0.47                       |
| 21     | <i>A. amazonica</i> | Absence    | Positive      | <i>C. albicans</i>       | 0.36                    | 0.54                       |
| 22     | <i>A. aestiva</i>   | Absence    | Positive      | <i>C. guilliermondii</i> | 0.45                    | 0.75                       |
| 23     | <i>A. aestiva</i>   | Absence    | Positive      | <i>C. humicola</i>       | 0.25                    | 1                          |
| Mean   |                     |            |               |                          | 0.28                    | 0.75                       |

<sup>a</sup> Pz = 1.0 = negative; 0.64 ≤ Pz < 1.00 = positive; Pz < 0.64 = strongly positive.

<sup>b</sup> Pz (Price et al., 1982) = 
$$\frac{\text{diameter of the colony}}{\text{total diameter of the colony plus precipitation zone}}$$

on readings taken on 7 days, having mean value Pz = 0.75 (Table 1).

## DISCUSSION

The birds selected for the study came from illegal trade, and being submitted to the stress of capture, transportation, overpopulation and inadequate feeding, many times these birds had to be treated with antibiotics in the recovery center. These predisposing factors may have made these birds more susceptible to infections caused by opportunistic fungi, what supports the high isolation rate of *Candida* spp. from the crop of the animals in this study (23/40; 57.5%).

There were no differences in the isolation of *Candida* spp. among the birds with or without ingluvitis; besides, the behavior of the yeasts was not different in relation to filamentation and production of exoenzymes. It was concluded that, yeasts isolated were acting as opportunistic microorganisms, producing virulence factors in parrots with and without ingluvitis. Since *Candida* species are considered part of the microflora of the gastrointestinal tract, debilitated condition of the animal is essential for *Candida* to settle and multiply (Mancianti et al. 2002).

Candidiasis is frequent in human patients showing impaired immune response (Bodey et al. 2002, Costa et al. 2006), in animals the same situation is observed. *C. rugosa* was isolated from young turkeys with concomitant chronic coccidiosis, and postmortem findings showed

excessive growth of the yeasts in the digestive tract of those birds, causing ulcerative lesions in the ventricle (Moretti et al. 2000). In samples of respiratory secretion from pigeons presenting cryptococcosis there were the concomitant isolation of *Candida* strains in about 15% of them (Bernardo et al. 1994).

Although, most veterinary texts consider *C. albicans* as the only species of the genus involved in the infections of the digestive tract of psittacines birds (Harrison 1986, Speer 1995, Schmidt et al. 2003), some researchers report species non-*albicans* of the genus *Candida* as responsible for infections in birds. *C. parapsilosis* has been reported as causing crop stasis, regurgitation, lethargy, weight loss, and diarrhea (Kano et al. 2001, Lamberski 2003); *C. krusei* and *C. tropicalis* have already been isolated from the digestive tract of psittacine birds, malnourished, incorrectly managed and with inhibited bacterial microbiota due to the prolonged use of systemic antibiotics (Schmidt et al. 2003). In none of these studies the pathogenicity and virulence factors of the isolates were studied.

Only two (8%) of the strains isolated in this project were identified as *C. albicans*; five species of the genus *Candida* were isolated from the crop of the parrots, including *C. guilliermondii*, *C. famata*, and *C. humicola*, which have not yet been reported as causing psittacine infection. Data related to the species isolated in this research, together with the low prevalence of *C. albicans*, show the importance

of the results obtained, for they do not comply with what was reported before, and corroborate the tendency to consider other species of the genus *Candida* as pathogenic for birds (Kano et al. 2001, Lamberski 2003). Since there are different susceptibility profiles among *Candida* species (Bodey et al. 2002, Pfaller et al. 2002, Costa et al. 2006), it is important to know which is the species involved in the infection to be successful in the treatment of the animals.

It should be emphasized that the different *Candida* species isolated from the parrots have already been reported in human infections (Pfaller et al. 2002, Costa et al. 2006), and that these birds could characterize as source of infection for other animals, and also for those people that manage them, such as caretakers, biologists, and veterinarians (Mancianti et al. 2002).

Almost half of the strains (44%) presented filamentation in the direct examination of the clinical sample; once the ability to filament is an indication for the pathogenicity of the isolates, a simple direct examination of the clinical sample Gram-stained may aid to understand the role the yeast plays in the animal analyzed (microflora or pathogen) (Barret-Bee et al. 1985, Koneman & Roberts 1990).

The basic constitution of the vertebrate's cellular membrane is a double layer of phospholipids interspersed with proteins. Exposure to proteinase and phospholipase produced by microorganisms induces pores on these membranes, dismantling all cellular functions and favoring tissue invasion. Therefore, the production of exoenzymes is considered an important virulence factor for microorganisms (Barret-Bee et al. 1985, Odds 1985, Dolan et al. 2004). All *Candida* strains isolated in this research produced proteinase and 68% of them produced phospholipase, reinforcing the pathogenic role of these yeasts in the cases studied.

Since parrots are part of the family that has the greatest number of endangered species (IUCN 2008), a better understanding of the diseases that affect them permit establishing prophylactic and curative measures that increase the survival rate of these birds.
